X-MET8000 Optimum Geo calibration datasheets

Hanna Heinonen (February 2019)

The information in this document applies to the X-MET8000 Optimum Geo only.

Science for
a better tomorrow

Definitions

Instrument limit of detection (IDL):

- The concentration that is required for an element to produce an x-ray signal (intensity) greater than three times the standard deviation of the noise (=background) level.

Method limit of detection (MDL):

- The minimum concentration of an element that can be measured and reported with 99% confidence that the element's concentration is greater than zero.
- It is calculated as per the procedure defined in Protocol 40 CFR Ch.1 Part 136 App B.

Note 1: The MDL is always larger than the IDL, as it takes into account errors due to the method/calibration itself (e.g. background subtraction, corrections for interfering elements....).

Note 2: All limits of detection are calculated for interference-free matrices. Limits of detection in a “real” sample will be higher.

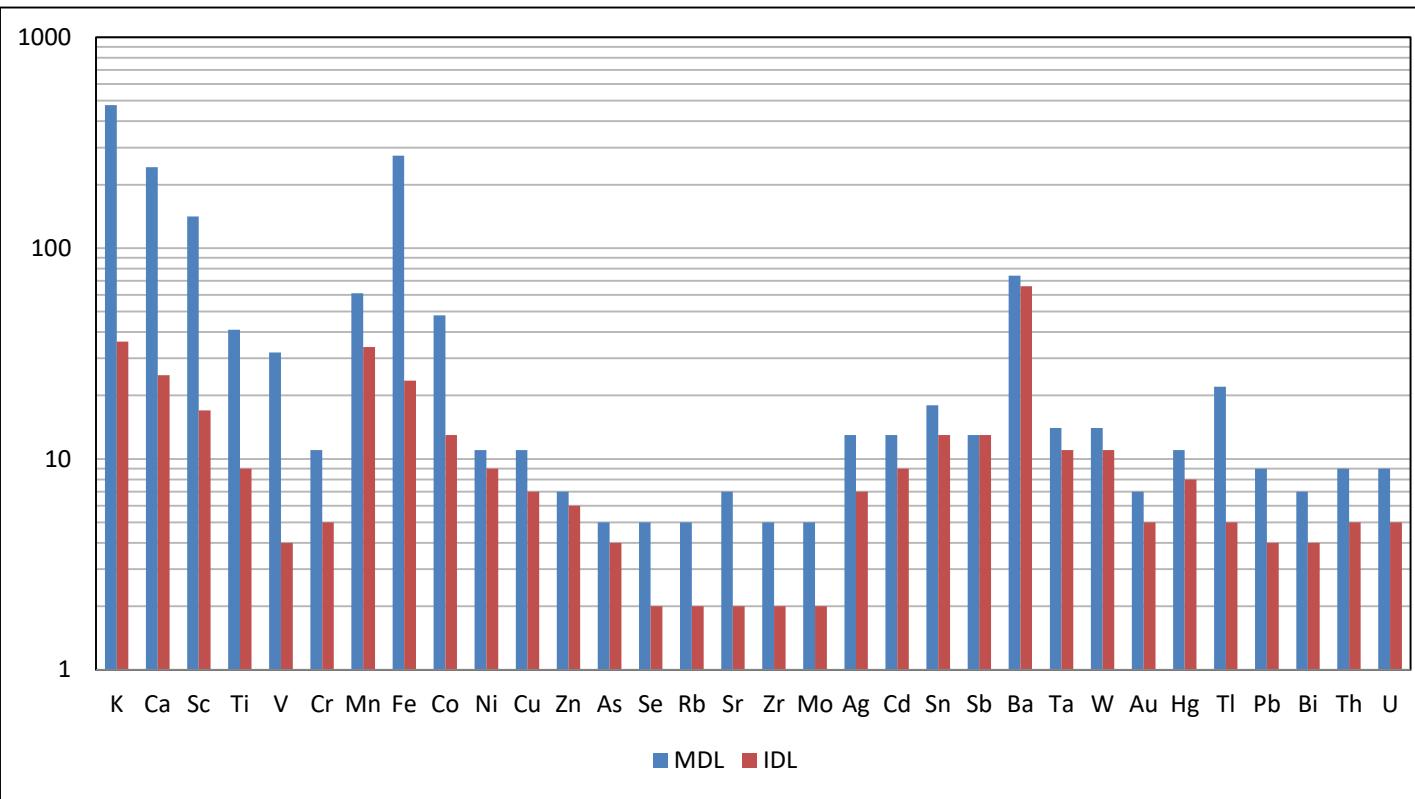

Soil application

- General FP method for the analysis of heavy metals in soil matrices.
- Suitable for samples with total heavy element content <10% and individual metal concentration < 1%.
- Does not include light elements.

Mining application

- Includes Mining FP and Mining LE FP.
- General method for analysing heavy elements in mining samples, where the total heavy element content is > 5% and individual metal concentration is > 1%.
- Mg, Al, Si, P and S are measured when the Light Elements are switched ON.
- CAUTION: light elements analysis is sensitive to sample form, i.e. samples need to be dried and ground for best accuracy.

Limits of detection (60s per condition), mg/kg

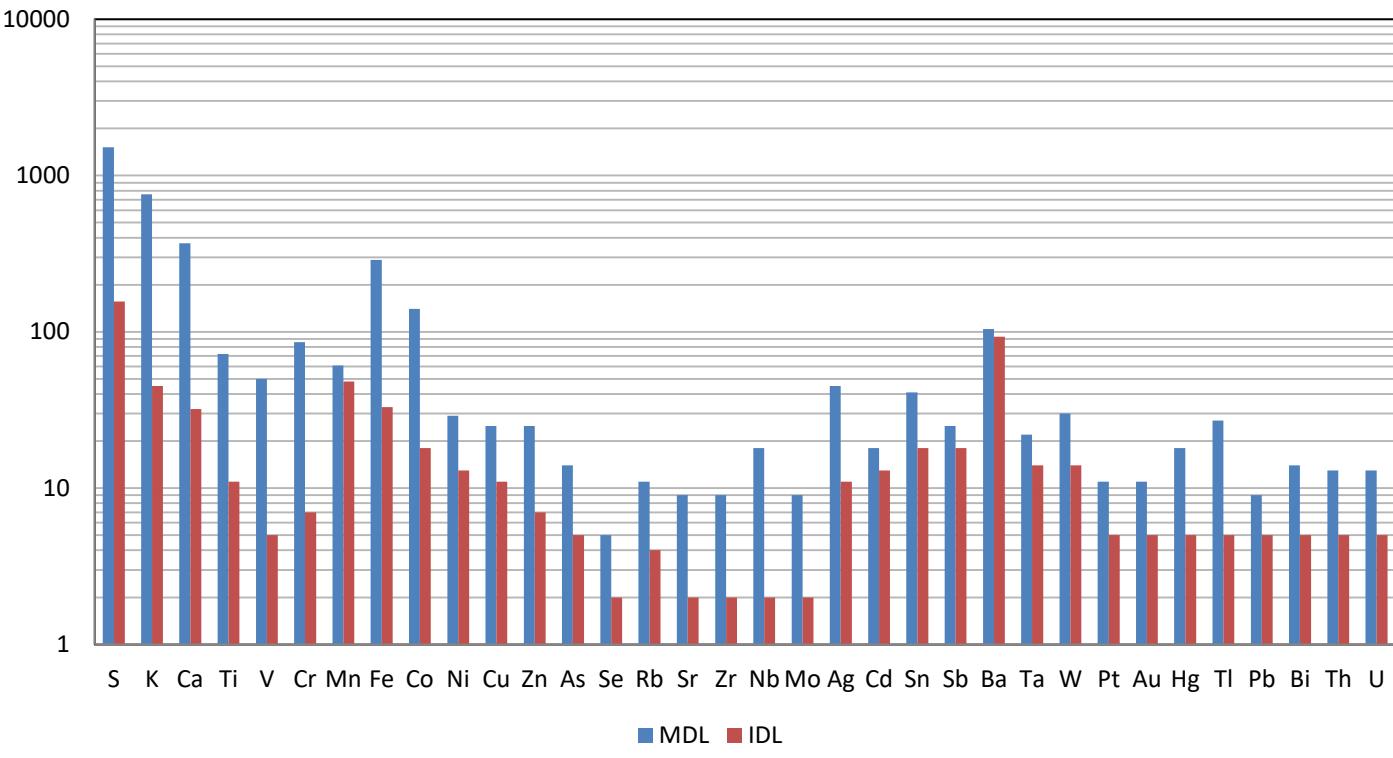

Typical accuracy and precision (60s total analysis time), wt%
